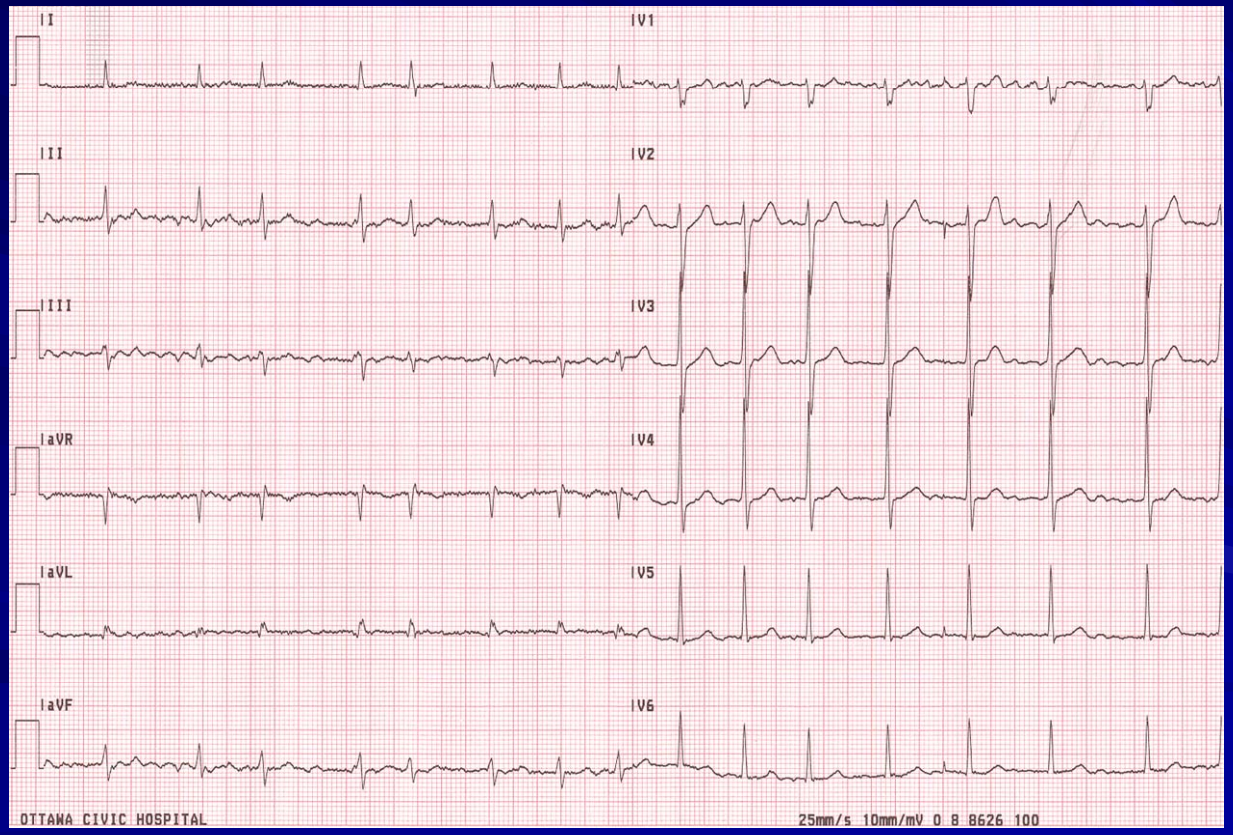
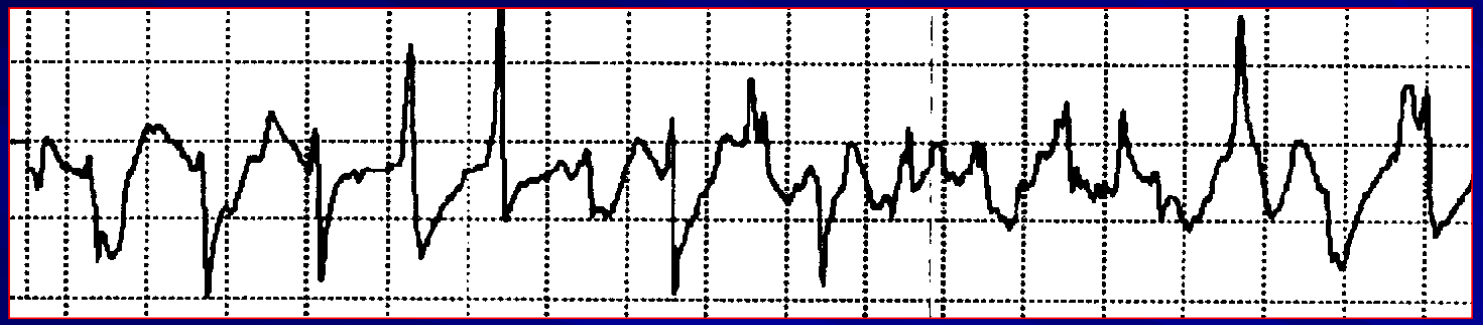
# The Big AF and Stroke Questions

- 1. What is atrial fibrillation?
- 2. What is stroke?
- 3. How does atrial fibrillation cause stroke?
- b. Does AF cause stroke, or is it simply a risk marker?
- 4. How does one prevent AF-related stroke?

# Atrial Fibrillation in Framingham

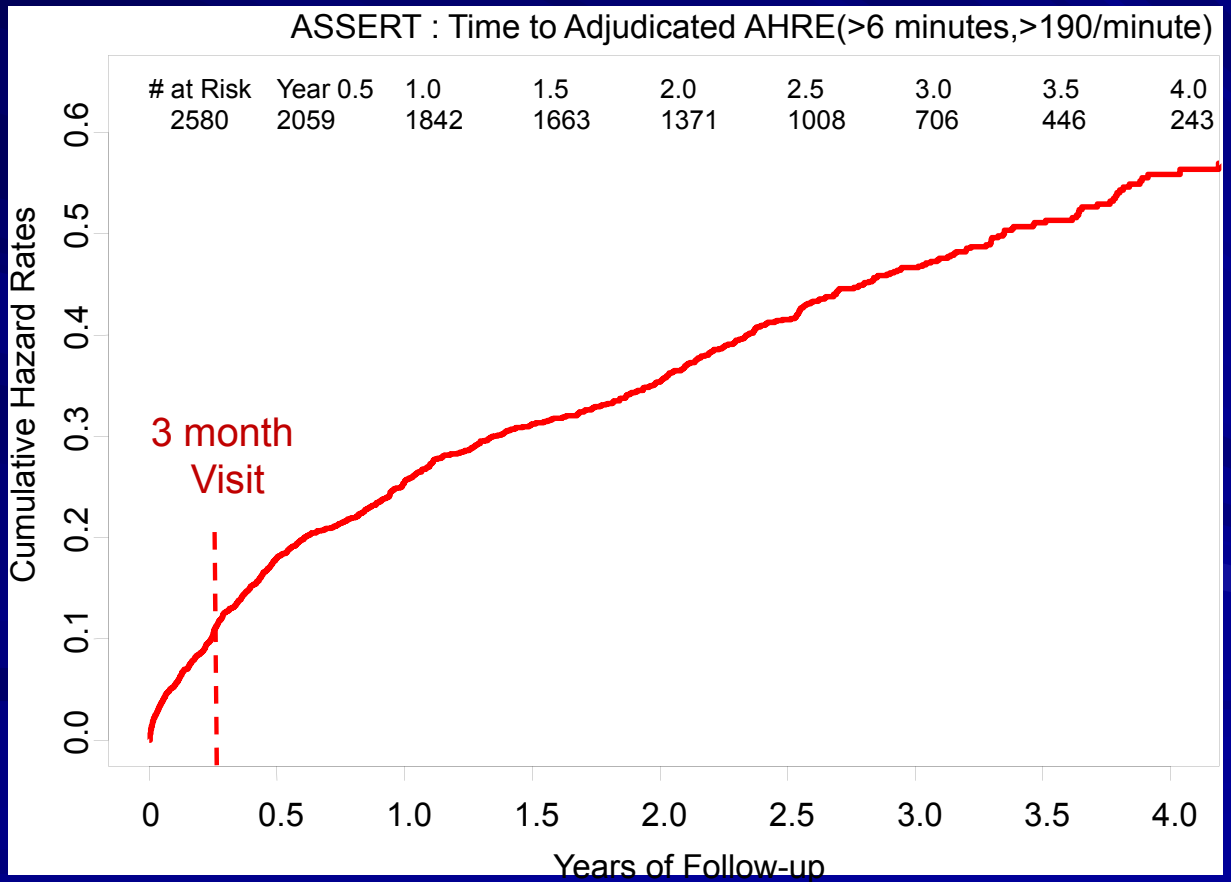


# Sub-Clinical AF Detected by Pacemakers



1. Mostly asymptomatic
2. Relatively short episodes detected only with long-term, continuous monitoring

# Time to First Device-Detected Atrial Tachyarrhythmia > 6 min, >190 bpm



# Are brief episodes of AF detected with long-term continuous monitoring associated with stroke?

How are they related?
How long must they be to increase stroke risk?

# ASSERT: Clinical Outcomes

Healey JS, NEJM 2012

| Event | Device-Detected Atrial Tachyarrhythmia | | | | Device-Detected Atrial Tachyarrhythmia Present vs. absent | | |
|---|---|---|---|---|---|---|---|
| | Absent N=2319 | | Present N= 261 | | | | |
| | events | %/year | events | %/ year | RR | 95% CI | p |
| Ischemic Stroke or Systemic Embolism | 40 | 0.69 | 11 | 1.69 | 2.49 | 1.28 – 4.85 | 0.007 |

| Systemic embolism | 16 (0.5) | 9 (0.5) | 7 (0.4) | 0.62 |
| Pulmonary embolism | 8 (0.3) | 2 (0.1) | 6 (0.5) | 0.16 |
| Hospitalization after base line | 2594 (76.6) | 1220 (73.0) | 1374 (80.1) | <0.001 |

*Percentages were derived from a Kaplan–Meier analysis. P values were derived from the log-rank statistic.

†The P value in the case of death was based on the square root of the log-rank statistic, adjusted for 10 interim monitoring analyses.

‡One patient had crossed over to the rhythm-control group and was taking quinidine, and one patient had torsade de pointes 72 hours after mitral-valve replacement.

§Information on warfarin therapy was missing for two patients in the rate-control group and three patients in the rhythm-control group. Information on the presence of atrial fibrillation with the event was missing for 16 patients in the rate-control group and 13 patients in the rhythm-control group.

AFFIRM: G. Wyse, NEJM 2002

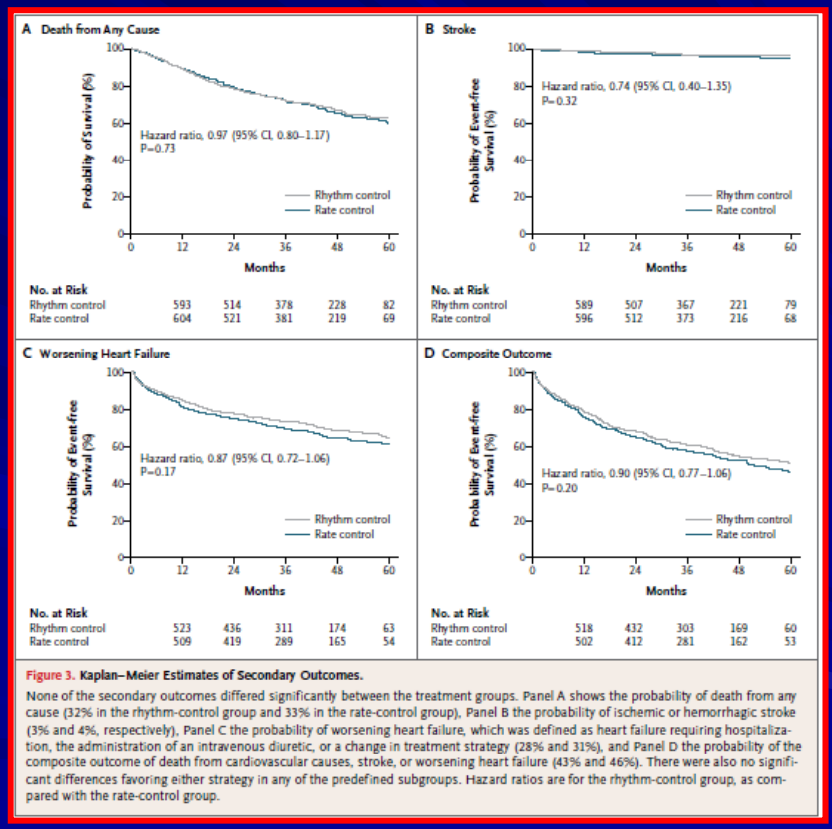

**Figure 3. Kaplan–Meier Estimates of Secondary Outcomes.**

None of the secondary outcomes differed significantly between the treatment groups. Panel A shows the probability of death from any cause (32% in the rhythm-control group and 33% in the rate-control group), Panel B the probability of ischemic or hemorrhagic stroke (3% and 4%, respectively), Panel C the probability of worsening heart failure, which was defined as heart failure requiring hospitalization, the administration of an intravenous diuretic, or a change in treatment strategy (28% and 31%), and Panel D the probability of the composite outcome of death from cardiovascular causes, stroke, or worsening heart failure (43% and 46%). There were also no significant differences favoring either strategy in any of the predefined subgroups. Hazard ratios are for the rhythm-control group, as compared with the rate-control group.

# Asymptomatic or silent AF following AF Ablation: DISCERN AF

ORIGINAL INVESTIGATION

ONLINE FIRST

## Discerning the Incidence of Symptomatic and Asymptomatic Episodes of Atrial Fibrillation Before and After Catheter Ablation (DISCERN AF)

*A Prospective, Multicenter Study*

*Atul Verma, MD, FRCPC; Jean Champagne, MD; John Sapp, MD; Vidal Essebag, MD, PhD; Paul Novak, MD; Allan Skanes, MD; Carlos A. Morillo, MD; Yaariv Khaykin, MD; David Birnie, MD*

**Background:** The DISCERN AF study (Discerning Symptomatic and Asymptomatic Episodes Pre and Post Radiofrequency Ablation of Atrial Fibrillation) monitored atrial fibrillation (AF) using an implantable cardiac monitor (ICM) to assess the incidence and predictors of asymptomatic AF before and after catheter ablation.

**Methods:** Patients with symptomatic AF underwent implantation of an ICM with an automated AF detection algorithm 3 months before and 18 months after ablation. Patients kept a standardized diary to record symptoms of arrhythmia, and ICM data were downloaded every 3 months. All episodes were blindly adjudicated and correlated with the diary. Asymptomatic recurrences were ICM episodes of 2 minutes or longer with no associated diary symptoms.

**Results:** Fifty patients had 2355 ICM episodes. Of these, 69.0% were true AF/atrial flutter (AFL)/atrial tachycardia (AT); 16.0%, sinus with extrasystoles; 11.0%, artifact; and 4.0%, sinus arrhythmia. Total AF/AFL/AT burden was reduced by 86% from a mean (SD) of 2.0 (0.5) h/d per patient before to 0.3 (0.2) h/d per patient after ablation ($P<.001$), and 56.0% of all episodes were asymptomatic. The ratio of asymptomatic to symptomatic AF episodes increased after ablation from 1.1 to 3.7 ($P=.002$). By symptoms alone, 29 of 50 patients (58%) were free of AF/AFL/AT after ablation compared with 23 of 50 (46%) using ICM-detected AF/AFL/AT recurrence. Asymptomatic episodes were more likely AFL/AT and were significantly shorter and slower, with lower heart rate variability. However, the postablation state was the strongest independent predictor of asymptomatic AF.

**Conclusions:** The ratio of asymptomatic to symptomatic AF episodes increased from 1.1 before to 3.7 after ablation. Postablation state is the strongest predictor of asymptomatic AF. Symptoms alone underestimate postablation AF burden, with 12% of patients having asymptomatic recurrences only.

Percutaneous closure of the left atrial appendage versus warfarin therapy for prevention of stroke in patients with atrial fibrillation: a randomised non-inferiority trial

David R Holmes, Vivek Y Reddy, Zoltan G Turi, Shephal K Doshi, Horst Sievert, Maurice Buchbinder, Christopher M Mullin, Peter Sick, for the PROTECT AF Investigators*

Lancet 2009; 374: 534-42

Summary

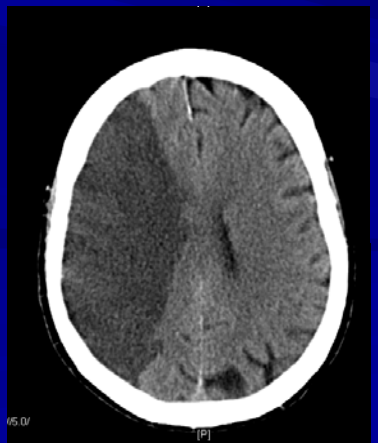
Background In patients with non-valvular atrial fibrillation, embolic stroke is thought to be associated with left atrial appendage (LAA) thrombi. We assessed the efficacy and safety of percutaneous closure of the LAA for prevention of stroke compared with warfarin treatment in patients with atrial fibrillation.

Methods Adult patients with non-valvular atrial fibrillation were eligible for inclusion in this multicentre, randomised non-inferiority trial if they had at least one of the following: previous stroke or transient ischaemic attack, congestive heart failure, diabetes, hypertension, or were 75 years or older. 707 eligible patients were randomly assigned in a 2:1 ratio by computer-generated randomisation sequence to percutaneous closure of the LAA and subsequent discontinuation of warfarin (intervention; n=463) or to warfarin treatment with a target international normalised ratio between 2·0 and 3·0 (control; n=244). Efficacy was assessed by a primary composite endpoint of stroke, cardiovascular death, and systemic embolism. We selected a one-sided probability criterion of non-inferiority for the intervention of at least 97·5%, by use of a two-fold non-inferiority margin. Serious adverse events that constituted the primary

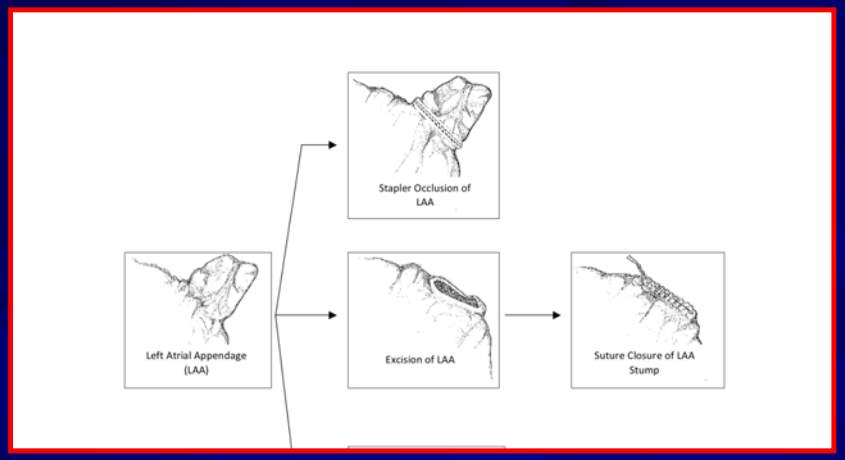
# LAA Thrombus and Stroke

- Most strokes (70%) in AF patients are cardio-embolic originating from the LAA
- At least 90% of the clots are in the LAA in AF patients

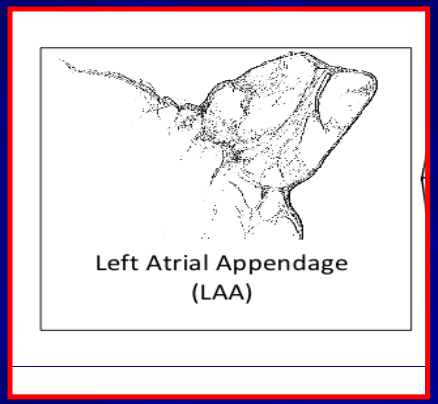
=



# LAAOS-III Trial



VS.



- Ongoing RCT (n=3700)
- Patients coming for routine CABG or valve surgery
- History of AF; on or off anticoagulation
- Randomized to LAA removal or control
- Currently, over 1000 patients, 25% not on anticoagulation
